
LinkedIn Teaser Post — NDN IPFS Chain / NDP v1.0 Coming Soon

Something we've been building for the past few months is about to change how teams think about IPFS in production.

The problem we've kept running into — and hearing about from other builders:

You need blob pinning. ☒ Fine.

You also need a model registry. ➡ Now you're juggling two providers.

You also need queryable user records. ➡ Now three.

Three providers. Three auth tokens. Three billing meters. No unified audit. Fragmented tooling everywhere.

We're about to collapse that stack.

Introducing the **NDN Data Protocol (NDP)** — one protocol for three database workloads on IPFS:

● **Blobs DB** — Pinning Services API v1.0 compatible out of the box

● **Models DB** — HuggingFace model mirroring + direct-to-GPU weight streaming

● **Structured DB** — Queryable JSON with schemas, immutable version chains, and content-addressed views

One credential. One billing meter. One audit trail across all three.

The technical foundation: every NDP object canonicalized via JCS (RFC 8785) before hashing. Same content → same CID, every time. Cross-provider portability is a protocol guarantee, not a marketing claim.

And here's the one enterprise teams keep asking about: GDPR right-to-erasure without repinning a petabyte. Delete the envelope key on-chain → every affected CID becomes permanently unreadable. Cryptographic proof of erasure.

NDP v1.0 spec drops publicly next week — CC-BY 4.0. Reference implementation — Apache-2.0. Any provider can implement it.

We're also applying to the **IPFS Foundation Grant Program** with NDP as the headline deliverable.

Follow this space. We'll be sharing the full spec and public repo link when it goes live.
